BACKGROUND

Chemokines are a family of cytokines that regulate the adhesion and transendothelial migration of leukocytes during an immune or inflammatory reaction (Mackay C.R., Nat. Immunol., (2001) 2:95; Olson et al., Am. J. Physiol. Regul. Integr. Comp. Physiol., (2002) 283:R7). Chemokines also regulate T cells and B cells trafficking and homing, and contribute to
10 the development of lymphopoietic and hematopoietic systems (Ajuebor et al., Biochem. Pharmacol., (2002) 63:1191). Approximately 50 chemokines have been identified in humans. They can be classified into 4 subfamilies, i.e., CXC, CX3C, CC, and C chemokines, based on the positions of the conserved cysteine residues at the N-terminal (Onuffer et al., Trends Pharmacol
15 Sci., (2002) 23:459). The biological functions of chemokines are mediated by their binding and activation of G protein-coupled receptors (GPCRs) on the cell surface. Take CXCR4 receptor for example, it can be activated by Stromal-derived factor-1 or SDF-1, a member of CXC chemokines.

SDF-1 was originally cloned from bone marrow stromal cell lines and found to act as a
20 growth factor for progenitor B cells (Nishikawa et al., Eur. J. Immunol., (1988) 18:1767). SDF-1 also induces bone marrow colonization of hematopoietic precursor cells during embryogenesis (Bleul et al., J. Exp. Med., (1996) 184:1101). The physiological function of SDF-1 is mediated by CXCR4 receptor. Mice lacking SDF-1 or CXCR4 receptor show lethal abnormality in bone marrow myelopoiesis, B cell lymphopoiesis, and cerebellar development (Nagasawa et al.,
25 Nature, (1996) 382:635; Ma et al., Proc. Natl. Acad. Sci., (1998) 95:9448; Zou et al., Nature (1998) 393:595; Lu et al., Proc. Natl. Acad. Sci. (2002) 99:7090). CXCR4 receptor is expressed

broadly in a variety of tissues, particularly in immune and central nervous systems, and has been described as the major co-receptor for HIV-1/2 on T lymphocytes. Although initial interest in CXCR4 antagonism focused on its potential application to AIDS treatment (Bleul et al., Nature (1996) 382:829), it is now becoming clear that CXCR4 receptor and SDF-1 are also involved in other pathological conditions such as rheumatoid arthritis, asthma, and tumor metastases (Buckley et al., J. Immunol., (2000) 165:3423). CXCR4 receptor and SDF-1 are also found widely expressed in many tissues during embryonic development. Further, the CXCR4/SDF-1 pathway has been shown to be critically involved in the regeneration of several tissue injury models. Specifically, it has been found that the SDF-1 level is elevated at an injured site and CXCR4-positive cells actively participate in the tissue regenerating process.

The polyamine compounds described in the summary section above can be prepared by methods well known in the art, including the synthetic routes disclosed herein.

For example, compound 1-11 can be respectively prepared by reacting tris(2-aminoethyl)amine with three equivalent amounts of a corresponding aldehyde, and followed by a reduction reaction using sodium borohydride.

In another example, one can react 1,4-dibromoxylene with two equivalent amounts of bis(*t*-butoxycarbonylaminoethyl)amine. The reaction mixture is subsequently treated with hydrochloric acid to give an intermediate, 1,4-di[bis(2-aminoethyl)aminomethyl]benzene. This intermediate can react with four equivalent amounts of corresponding aldehyde compounds and sodium borohydride to give compounds 12-14. Alternatively, this intermediate can react with two equivalent amounts of pyridine-2-carbaldehyde, and then with sodium borohydride to give compound 15. One can also react 1,4-dibromoxylene with one equivalent amount of bis(*t*-butoxycarbonylaminoethyl)amine and one equivalent amount of other amine compounds. Compounds 56-57, 65, 66, 68, 80, 86, 91, 93-95, and 106-109 can be prepared through this synthetic route, followed by sequential treatments with hydrochloric acid, two equivalent amounts of a corresponding aldehyde, and sodium borohydride. In a similar manner, compounds 49 can be prepared by reacting 1,4-dibromoxylene with one equivalent amount of tri-*t*-butoxycarbonyl protected cyclam and one equivalent amount of bis(2-pyridyliminoethyl)amine, followed by a reduction reaction using sodium borohydride.

In another example, compounds 16-48, 58-64, 69-79, 81-85, 87-90, 92, 96-105, 115, 121, 122, 125, and 126 can be synthesized using the following synthetic route. One can react 4-cyanobenzylbromide with one equivalent amount of bis(*t*-butoxycarbonylaminoethyl)amine and then hydrochloric acid to give 4-[bis(2-aminoethyl)amino-methyl]-benzonitrile. This benzonitrile can then be treated sequentially with two equivalent amounts of an aldehyde,

methyl]-benzaldehyde. The just-mentioned compounds can then be prepared by treating this benzaldehyde sequentially with one equivalent amount of a corresponding amine, sodium borohydride, and hydrochloric acid. Compounds 110, 111, 116, 117, 120, 123, and 124 can be prepared in a similar manner except that the benzonitrile is treated with one equivalent amount of an aldehyde and one equivalent amount of a ketone.

In another example, one can react 4-bromomethylbenzenesulfonyl chloride with one equivalent amount of an amine and then one equivalent amount of bis(*t*-butoxycarbonylaminoethyl)amine. An intermediate is then obtained after treating the above reaction mixture with hydrochloric acid. Compounds 51-55 can then be respectively prepared by treating this intermediate with a corresponding aldehyde and followed with sodium borohydride. Compounds 50, 67, 112, and 113 can be prepared using the same procedure as that of compounds 51-55 except that 4-bromomethylbenzenesulfonyl chloride is treated with two equivalent amounts of bis(*t*-butoxycarbonylaminoethyl)amine.

In another example, one can react 4-cyanobenzaldehyde sequentially with one equivalent amount of 2-methyl-2-aminoethanol, sodium borohydride, and 2-(2-bromo-ethoxy)-tetrahydropyran to obtain a substituted aminomethylbenzonitrile. Upon removal the tetrahydropyranyl protection group, the benzonitrile can be sequentially mesylated and treated with 2-aminomethylpyridine. After the resultant secondary amine is protected, the benzonitrile can then be treated with diisobutylaluminum, one equivalent amount of a corresponding amine, sodium borohydride, triflic acid, and hydrochloric acid to obtain compounds 114, 118, and 119.

A polyamine compound thus synthesized can be further purified by a method such as column chromatography, high-pressure liquid chromatography, or recrystallization.

Other polyamine compounds can be prepared using other suitable starting materials through the above synthetic routes and others known in the art. The methods described above may also additionally include steps, either before or after the steps described specifically herein, to add or remove suitable protecting groups in order to ultimately allow synthesis of the polyamine compounds. In addition, various synthetic steps may be performed in an alternate sequence or order to give the desired compounds. Synthetic chemistry transformations and protecting group methodologies (protection and deprotection) useful in synthesizing applicable polyamine compounds are known in the art and include, for example, those described in R. Larock, *Comprehensive Organic Transformations*, VCH Publishers (1989); T.W. Greene and

P.G.M. Wuts, *Protective Groups in Organic Synthesis*, 2nd Ed., John Wiley and Sons (1991); L. Fieser and M. Fieser, *Fieser and Fieser's Reagents for Organic Synthesis*, John Wiley and Sons (1994); and L. Paquette, ed., *Encyclopedia of Reagents for Organic Synthesis*, John Wiley and Sons (1995) and subsequent editions thereof.

5 The polyamine compounds mentioned herein may contain a non-aromatic double bond and one or more asymmetric centers. Thus, they can occur as racemates and racemic mixtures, single enantiomers, individual diastereomers, diastereomeric mixtures, and cis- or trans- isomeric forms. All such isomeric forms are contemplated.

10 Also within the scope of this invention is a pharmaceutical composition contains an effective amount of at least one polyamine compound described above and a pharmaceutical acceptable carrier. Further, this invention covers a method of administering an effective amount of one or more of the polyamine compounds to a patient having a disease described in the summary section above. This invention also covers a method of administering an effective amount of one or more of the polyamine compounds for enhancing migration of bone marrow-
15 derived cells to blood. "An effective amount" refers to the amount of an active polyamine compound that is required to confer a therapeutic effect on the treated subject. Effective doses will vary, as recognized by those skilled in the art, depending on the types of diseases treated, route of administration, excipient usage, and the possibility of co-usage with other therapeutic treatment.

20 To practice the method of the present invention, a composition having one or more polyamine compounds can be administered parenterally, orally, nasally, rectally, topically, or buccally. The term "parenteral" as used herein refers to subcutaneous, intracutaneous, intravenous, intramuscular, intraarticular, intraarterial, intrasynovial, intrasternal, intrathecal, intralesional, or intracranial injection, as well as any suitable infusion technique.

25 A sterile injectable composition can be a solution or suspension in a non-toxic parenterally acceptable diluent or solvent, such as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that can be employed are mannitol, water, Ringer's solution, and isotonic sodium chloride solution. In addition, fixed oils are conventionally employed as a solvent or suspending medium (e.g., synthetic mono- or diglycerides). Fatty acid, such as oleic
30 acid and its glyceride derivatives are useful in the preparation of injectables, as are natural pharmaceutically acceptable oils, such as olive oil or castor oil, especially in their

polyoxyethylated versions. These oil solutions or suspensions can also contain a long chain alcohol diluent or dispersant, carboxymethyl cellulose, or similar dispersing agents. Other commonly used surfactants such as Tweens or Spans or other similar emulsifying agents or bioavailability enhancers which are commonly used in the manufacture of pharmaceutically acceptable solid, liquid, or other dosage forms can also be used for the purpose of formulation.

A composition for oral administration can be any orally acceptable dosage form including capsules, tablets, emulsions and aqueous suspensions, dispersions, and solutions. In the case of tablets, commonly used carriers include lactose and corn starch. Lubricating agents, such as magnesium stearate, are also typically added. For oral administration in a capsule form, useful diluents include lactose and dried corn starch. When aqueous suspensions or emulsions are administered orally, the active ingredient can be suspended or dissolved in an oily phase combined with emulsifying or suspending agents. If desired, certain sweetening, flavoring, or coloring agents can be added.

A nasal aerosol or inhalation composition can be prepared according to techniques well known in the art of pharmaceutical formulation. For example, such a composition can be prepared as a solution in saline, employing benzyl alcohol or other suitable preservatives, absorption promoters to enhance bioavailability, fluorocarbons, and/or other solubilizing or dispersing agents known in the art.

A composition having one or more active polyamine compounds can also be administered in the form of suppositories for rectal administration.

The carrier in the pharmaceutical composition must be "acceptable" in the sense that it is compatible with the active ingredient of the composition (and preferably, capable of stabilizing the active ingredient) and not deleterious to the subject to be treated. One or more solubilizing agents can be utilized as pharmaceutical excipients for delivery of an active polyamine compound. Examples of other carriers include colloidal silicon oxide, magnesium stearate, cellulose, sodium lauryl sulfate, and D&C Yellow # 10.

The polyamine compounds described above can be preliminarily screened for their efficacy in treating above-described diseases by an *in vitro* assay (See Example 127 below) and then confirmed by animal experiments and clinic trials. Other methods will also be apparent to those of ordinary skill in the art.

The specific examples below are to be construed as merely illustrative, and not limitative of the remainder of the disclosure in any way whatsoever. Without further elaboration, it is believed that one skilled in the art can, based on the description herein, utilize the present invention to its fullest extent. 1,4-Dibromoxylene (13.64 mmol) was treated with bis(*tert*-butoxyaminoethyl)amine (2.74 mmol) in the presence of Et₃N (2.74 mmol) in CH₂Cl₂ (50 mL) at 0 °C. After stirring for 16 h, the solution was filtered, concentrated, and purified to afford a mono-substituted bromide. This mono-substituted bromide (0.68 mmol) was reacted with 6-methoxy-1,2,3,4-tetrahydro-9H-pyrido[3,4-b]indole (0.68 mmol) in CH₃CN (10 mL) in the presence of K₂CO₃ (3.39 mmol) at 60 °C. After stirring for 12 h, the solution was filtered and the filtrate was concentrated and purified by chromatography to give a Boc-protected residue (0.57 mmol; 84% yield). This residue (0.26 mmol) was treated with HCl/ether and neutralized to give a polyamine. This polyamine was then treated with the pyridine-2-carbaldehyde to give a Schiff base. The Schiff base was reduced by NaBH₄ in MeOH. The crude product thus obtained was purified by alumina column chromatography (EtOAc/MeOH = 7:3) to afford compound 56.

Example 127: *in vitro* assay

Compounds 1-126 were tested for their efficacy in binding to CXCR4 receptor using a DELFIA GTP-binding kit (Wallac Oy, Turku, Finland). The DELFIA GTP-binding assay is a
10 time-resolved fluorometric assay based on GDP-GTP exchange on G-protein subunits followed by activation of a G protein-coupled receptor by its agonists. Eu-GTP, obtained from Wallac Oy, was used in this assay to allow monitoring of agonist-dependent activation of G-protein. Stimulation of CXCR4 receptor by SDF-1 leads to the replacement of GDP by GTP on the α -subunit of G-protein. This GTP-G α complex represents the activated form of G-protein. Eu-
15 GTP, a non-hydrolysable analog of GTP, can be used to quantify the amount of activated G-protein. (Peltonen et al., Eur. J. Pharmacol. (1998) 355:275.)

Plasma membrane of CXCR4-expressing HEK293 cells was suspended in an assay buffer (50 mM NaCl, 100 μ g/mL saponin, 3 mM $MgCl_2$, 3 μ M GDP, 5% BSA, 50 mM HEPES, pH 7.4). An aliquot (4 μ g protein) was added to each well of an AcroPlate (Pall Life Sciences, Ann
20 Arbor, MI). After the addition of the test compounds (10 μ M in 0.1% DMSO) and stromal-derived factor-1 (4 nM in the assay buffer), the assay plate was incubated in the dark at room temperature with slow shaking for 10 minutes. Eu-GTP was added to each well and the plate was incubated again for 60 minutes. The assay was terminated by washing the plate twice with a wash solution provided in the assay kit. Binding of Eu-GTP was determined based on the
25 fluorescence signal from a Victor 2 multi-label reader.

Unexpectedly, all of the tested compounds showed IC_{50} values lower than 10 μ M. Specifically, 97 of the test compounds showed IC_{50} values lower than 1 μ M. Among them, 56 showed IC_{50} values between 0.004 μ M and 0.1 μ M.
